Whitefly and Lace Bug Performance on *Lantana* spp. Cultivars in the Greenhouse¹

Monica L. Townsend, Ronald D. Oetting, and S. Kristine Braman

*Department of Entomology, University of Georgia*
*College of Agriculture and Environmental Sciences*
*Georgia Experiment Station, Griffin, GA 30223*

**Abstract**

Performance of greenhouse whitefly, silverleaf whitefly, and lantana lace bug for eleven cultivars of *Lantana* spp. was assessed in greenhouse experiments. Insect population growth was monitored for seven weeks in three experiments. Relative damage at three weeks post-infestation with lantana lace bug was also evaluated. All cultivars supported growth and development of all insect species evaluated. Initial population development occurred differentially on cultivars with larger leaves, e.g., ‘Miss Huff’ and ‘Confetti’. However, by week seven all cultivars supported high populations of greenhouse and silverleaf whitefly and lantana lace bug.

**Index words:** host plant resistance, integrated pest management, IPM, silverleaf whitefly, greenhouse whitefly, lantana lace bug.

**Significance to the Nursery Industry**

No evidence for complete resistance among lantana cultivars examined was found. However, an apparent preference for certain cultivars suggests a potential monitoring strategy to facilitate early detection of potential insect pest problems in production and landscape settings. Greenhouse and silverleaf whitefly populations in the greenhouse increased more rapidly on ‘Miss Huff’, ‘Confetti’, and ‘Radiation’, the large-leaf cultivars. ‘Dallas Red’ demonstrated the least susceptibility to both species of whitefly. Similarly, pest population establishment on the other small-leaf cultivars ‘New Gold’, ‘Cream Mound’, and ‘Lemon Drop’ was comparatively delayed. ‘Miss Huff’, ‘Confetti’, ‘Irene’, and ‘Pink Caprice’ experienced the highest initial lace bug population growth, also suggesting that these large-leaf cultivars may serve as indicator plants for these pests in commercial production or in the landscape.

**Introduction**

The perennial shrub, *Lantana camara* L. (Verbenaceae) is a native of the tropical and subtropical Americas. In some areas (e.g., Australia, South Africa), since its introduction as an ornamental, it has escaped and is now considered a pest (3, 4). However, the highly colored flowers and attractiveness to butterflies and hummingbirds have made this species valuable in residential landscape settings. Lantana is prone to infestation by lace bug and whiteflies in the landscape and in greenhouses, respectively. The greenhouse whitefly,

Trialeurodes vaporariorum (Westwood) and the silverleaf whitefly, Bemisia argentifolii Bellows and Perring, are important pests of ornamental plants and other agricultural crops (8). Nymphal stages and adults extract plant sap and excrete honeydew, which contributes to the growth of unattractive sooty mold. Insecticides are the most commonly used method to suppress whitefly infestations on greenhouse-grown ornamental plants (5). Whiteflies are less problematic in the landscape than other pests, but they can still cause economic and environmental costs in the nursery and greenhouse. Insect management strategies are important in controlling whitefly populations and reducing their impact on plant health. 

Materials and Methods

Greenhouse and silverleaf whitefly, experiment 1. Lantana were transplanted into 6 in ultra azalea plastic pots and granular fertilizer was added to pots at planting. Subsequently, plants were fertilized two times per week with Peter’s 20:10:20 (Scotts, Marysville, OH). Plants were placed on the greenhouse benches and greenhouse whiteflies were released into the greenhouse.

Trialeurodes vaporariorum (Westwood) and the silverleaf whitefly, Bemisia argentifolii Bellows and Perring, are important pests of ornamental plants and other agricultural crops (8). Nymphal stages and adults extract plant sap and excrete honeydew, which contributes to the growth of unattractive sooty mold. Insecticides are the most commonly used method to suppress whitefly infestations on greenhouse-grown ornamental plants (5). Whiteflies are less problematic in the landscape. Lantana lace bug, Teleonemia scrupulosa (Stal), extracts plant sap causing a stippled or bleached appearance in affected foliage and reduced bloom. Plants are further disfigured by tar-like fecal deposits.

Host plant resistance is a valuable integrated pest management strategy. Insect and disease problems and associated economic and environmental costs in the nursery and landscape can be minimized by selecting relatively pest-resistant species or varieties that are well suited to local growing conditions. Publications listing ornamental plants with documented resistance to specific insects and diseases (10) assist and encourage propagation, use, supply and demand for resistant varieties. Resistance among plant species and cultivars to some key pests of ornamentals has been identified (e.g., 1, 2, 6, 7, 9, 11, 12). Often, however, resistance properties of available cultivars to key pests are not well characterized. Studies were conducted to determine the potential for resistance to whiteflies and lace bugs among ten lantana cultivars currently in commercial production and one experimental cultivar.

Materials and Methods

Greenhouse and silverleaf whitefly, experiment 1. Lantana were transplanted into 6 in ultra azalea plastic pots and granular fertilizer was added to pots at planting. Subsequently, plants were fertilized two times per week with Peter’s 20:10:20 (Scotts, Marysville, OH). Plants were placed on
greenhouse benches in a randomized complete block design with six replications. Plants were inoculated in separate greenhouses with either greenhouse whitefly (greenhouse 1) or silverleaf whitefly (greenhouse 2) by placing infested leaves (approximately 50 individuals per plant) directly on experimental plants. Insect populations were allowed three weeks to establish. Populations were monitored by counting the number of adults, immatures, and exuviae (pupal remains following adult emergence) per 15 leaves per plant every week for five weeks beginning week three through week seven. Cultivars evaluated included ‘Miss Huff’, ‘Confetti’, ‘Irene’, ‘New Gold’, ‘Radiation’, ‘Lemon Drop’, ‘Cream Mound’, ‘Pink Caprice’, and ‘Dallas Red’.

Greenhouse whitefly, experiment 2. Three cultivars were selected that had demonstrated the highest, medium, and lowest population levels of whiteflies during the previous trial. High population ‘Miss Huff’, medium ‘Radiation’, and low ‘Cream Mound’ were the three cultivars selected for further study. An experimental lantana cultivar ‘Mabel Rogers’ was also included in this trial. Rooted cuttings were transplanted into gallon pots, fertilized with osmocote and maintained as described previously. A randomized complete block design with six replications was arranged on greenhouse benches adjacent to lantana infested with greenhouse whitefly (approximately 8.6 m from greenhouse source of whitefly inoculum) This allowed each cv equal opportunity to become infested. Population levels were determined weekly for six weeks.

Lantana lace bug, experiment 3. Rooted cuttings of eleven cultivars; ‘Miss Huff’, ‘Irene’, ‘Pink Caprice’, ‘Mabel Rogers’, ‘Confetti’, ‘Red’, ‘Radiation’, ‘Purple Trailing’, ‘New Gold’, ‘Cream Mound’, and ‘Lemon Drop’ were transplanted into gallon sized pots, fertilized with osmocote and maintained as described previously. A randomized complete block design with six replications was arranged on greenhouse benches adjacent to lantana infested with greenhouse whitefly (approximately 8.6 m from greenhouse source of whitefly inoculum). This allowed each cv equal opportunity to become infested. Population levels were determined weekly for six weeks.

Results and Discussion

Greenhouse whitefly, experiment 1. Three weeks after inoculation greenhouse and silverleaf whiteflies were more numerous on the large-leaf cultivars ‘Miss Huff’, ‘Radiation’ ‘Irene’ and ‘Confetti’ (Tables 1 and 2). The small-leaf cultivars: ‘Cream Mound’, ‘Pink Caprice’, ‘New Gold’, ‘Lemon Drop’, and ‘Dallas Red’ during the first weeks of the trial did not support the same high population level of greenhouse or silverleaf whitefly as their large-leaf counterparts. Our experimental design did not allow us to determine whether this was a preference by adult whiteflies for oviposition sites, or differential nutritional suitability among cultivars. By week seven, all cultivars did support high population levels of greenhouse and silverleaf whiteflies in all life stages.

Greenhouse whitefly, experiment 2. Three cultivars that demonstrated high, medium, and low whitefly populations, ‘Miss Huff’, ‘Radiation’, and ‘Cream Mound’, respectively, from the first trial were tested along with an experimental variety ‘Mabel Rogers’. Few apparent differences were observed in number of adults or immatures on cultivars selected for the second trial with greenhouse whitefly (Table 3). Week 1 counts of the adults did show a slight preference for ‘Miss Huff’ and the experimental ‘Mabel Rogers’ but by week 6 no significant differences were seen among any of the cultivars examined. Immature populations followed the same trend as adults. ‘Miss Huff’ and the experimental cultivar had the highest populations of adults and immatures during the testing period.

*Lantana lace bug, experiment 3.* Three weeks after infestation with lantana lace bugs, all eleven cultivars supported some level of population growth (Table 4). Nymphs and adult lace bugs were found on all cultivars. Average total lace bugs per quadrant per plant ranged from 8.0 (‘Irene’) to 69.8 (‘Confetti’). Percent damage ranged from 26% (‘Lemon Drop’) to 79% (‘Miss Huff’) and was significant (p ≤ 0.05) (Table 5). Small-leaf cultivars ‘Lemon Drop’, ‘Cream Mound’, ‘Purple Trailing’ and ‘New Gold’ exhibited much less damage than other large-leaf cultivars during this initial infestation period. 

Seven weeks post-infestation all cultivars supported lace bug populations (Table 4). Small-leaf cultivars became heavily infested as the trial progressed at the decline of their larger leaved counterparts. All plants at the seven-week assessment exhibited 100% damage measured as number of infested leaves divided by total number of leaves. ‘Miss Huff’, ‘Confetti’ and ‘Irene’ were the first cultivars to become heavily infested with both lantana lace bug and whitefly. These cultivars were also the first to show noticeable damage. While it was beyond the scope of this study to clarify the mechanism underlying greater populations on large leaved cultivars, it is possible that these cultivars could all be used as monitor plants either in landscapes or in commercial production. These ‘indicator’ plants would alert the pest manager to first occurrence of lace bug and whiteflies as an early warning of pest populations. Although smaller leaved cultivars were less preferred by whiteflies or lacebugs, when planted in monoculture situations in greenhouse or landscape settings, our data indicate that they will support populations capable of inflicting significant damage.
