Introduction

Integrated pest management (IPM) is an essential part of any successful peanut program. The interactions between multiple pest species and crop/pest management strategies are complex. Production and pest management costs can vary considerably and influence a grower’s decision to employ certain management practices. Growers and their advisors may have a difficult time weighing the positive and negative impacts of different strategies. Many important peanut pest management decisions must be made prior to planting.

Project PI’s at North Carolina State University and Virginia Polytechnic University have developed a comprehensive website (www.peanut.ncsu.edu) and web-based decision support system (www.peanut.ncsu.edu/risk/) to assist growers in Virginia and North Carolina who are involved in the production of Virginia-Carolina (VC) – type peanuts.

Objectives

1. Decision Aid: To help growers and their advisors in assessing potential risks and benefits of competing management strategies.
2. Website: To help these stakeholders identify and manage pests, as well as provide copies of pest management documents.

Materials and Methods

The website aims to be a clearinghouse for all information related to production of VC-type peanut. Project PI’s created over 40 individual information sheets that detail (using text, tables and photos) various production and management topics (e.g., planting, harvest, and maturity), including identification and control of important diseases and insects. Each of these sheets is available via .html or .pdf formats on the website. Weed identification sheets from The Virginia Tech Weed Identification guide (www.vtaes.vt.edu/weedindex.htm) are also available through the site. The website also features a key word index that links like-publications and topics, alerts about timely production issues during the growing season, individual personnel pages for various university employees involved with peanut production, and links to extension publications (management summaries, articles, manuals, and reports).

The Decision Aid

The information sheets

Demonstration & Evaluation

Both the decision aid and website were demonstrated to extension agents and growers in NC and VA through field days and workshops. Test plots were established in 2008 & 2009 to evaluate differences in SCR and Sclerotinia Blight. Project PI’s demonstrated the utility of the program using posters, live computer demonstrations, and field plots while discussing the resulting risk indices for various pests.

In an effort to validate the decision aid, field surveys were completed by extension agents using real pest management scenarios from peanut fields located in their counties from 2008-2010. Pre-season agronomic information was collected about each field (including pesticide use and known field histories of pests). Follow-up surveys were completed to evaluate the end-of-year pest incidence and severity. This information will validate that the decision aid is accurate in making predictions.

Finally, the website and decision aid were demonstrated to extension agents from NC & VA in a workshop in 2010. Agents were able to view the various features of both programs, ask questions, and make recommendations.

Significance to NC Growers

This decision aid can help farmers reduce risk and maintain and possibly increase yields and economic return by allowing them and their advisors compare multiple production and pest management practices prior to implementation of a comprehensive strategy in the field. Additionally, this decision aid has the potential for growers and their advisors to embrace new technologies and management strategies more quickly and in some cases with greater precision than before.

The Peanut CRSP project LAG-00-96-90013.00 provided partial funding for this research.
